1 Introduction

Fine-grained vehicle classification, which differentiates between various types, makes, and models of cars, presents significant challenges. This difficulty arises from the large number of visually similar vehicle categories, variations in lighting and weather conditions, occlusions, and the diverse viewpoints from which vehicles may be captured. As a result, building a robust vehicle classification system requires a model capable of recognizing subtle visual cues while generalizing across highly variable real-world conditions.

In this project, we aim to explore and compare different strategies for hierarchical image classification on the Stanford Cars Dataset (Krause et al., 2013). The dataset contains 16,185 high-resolution images labeled with three hierarchical attributes: vehicle make, vehicle type, and vehicle model. These labels naturally form a multi-level taxonomy, making the dataset well-suited for studying hierarchical classification approaches.

Our baseline approach uses a ResNet-50 model pretrained on ImageNet as the backbone architecture. Initially, we treat the problem as a flat classification task by predicting the complete car label (containing make, type, and model) as a single class among 196 possible categories. This serves as our starting point for evaluating how well a standard single-head classifier performs on fine-grained classification without explicit hierarchical structure.

Building on this baseline, the primary objective of this project is to investigate how different hierarchical output designs influence classification performance. Specifically, we focus on three classification strategies:

1. **Single-head (flat) classifier:** Predicts the entire label (make, type, and model) as one combined class. This ignores the hierarchical relationships.
2. **Two-head classifier:** One head predicts the vehicle make, while the second head predicts the combined type+model label.

*Use footnote for providing further information about author (webpage, alternative address)—*not* for acknowledging funding agencies.

3. **Three-head classifier:** Predicts make, type, and model independently using three parallel classification heads.

After we evaluated these 3 variants, we will further enhance their performance using targeted regularization and optimization strategies. These include data augmentation, dropout, weight decay, and learning-rate adjustments, all of which can help reduce overfitting.

2 Related Work

Since the Stanford Cars dataset is popular, it is possible to find plenty prior work, trying to achieve high accuracy for classification by using different types of models and strategies.

The paper A Systematic Evaluation of Recent Deep Learning Architectures for Fine-Grained Vehicle Classification by Valev et al. investigates how modern convolutional neural networks perform on the Stanford Cars dataset. The authors evaluate several well-known CNN architectures, including VGG16, Inception, MobileNet, and multiple residual networks, with an emphasis on ResNet-50, ResNet-152, and DenseNet variants. Their study focuses entirely on flat fine-grained classification, meaning that each car is classified directly into one of 196 labels. The method does not employ any form of hierarchical structure such as predicting make or type separately. ResNet-50 is tested both when trained from scratch and when fine-tuned from ImageNet weights. Training ResNet-50 from scratch yields an accuracy of 84.3%, whereas fine-tuning dramatically improves performance to 92.0%. The deeper ResNet-152 shows similar behavior and achieves only 35.3% when trained from scratch but rises to 92.6% when fine-tuned. Among all evaluated CNNs, the best performing model is DenseNet-161, which reaches 94.6% accuracy on the Stanford Cars dataset. Their experiments highlight the importance of data augmentation such as horizontal flipping and motion blur, which add up to meaningful improvements. The paper does not consider hierarchical labels or multi-head predictions that leverage the natural make-type-model structure of the dataset. (<https://arxiv.org/pdf/1806.02987>)

The paper FineGrained Image Classification for Vehicle Makes & Models using CNNs explores the challenge of distinguishing highly similar car models within the Stanford Cars dataset. For their approach, they rely on transfer learning with a VGG-16 backbone pretrained on ImageNet. Two model variants are evaluated: a baseline that fine-tunes only the fully connected layers, and an improved architecture that removes one of the original fully connected layers, reduces the dimensionality of the remaining layers, and introduces dropout for regularization. The authors apply extensive data augmentation. Their method predicts all 196 classes as a single flat classification task. The experimental results show that the baseline VGG-16 achieves only 52.1% accuracy on the test set, while the modified VGG-16 reaches a much stronger accuracy of 84.0. These findings demonstrate that fine-tuned CNN backbones, combined with aggressive augmentation and streamlined classification heads, can perform competitively on fine-grained vehicle recognition tasks. (https://cs230.stanford.edu/projects_spring_2019/reports/18681590.pdf)

Our approach follows a similar foundation in that we also rely on transfer learning, starting from a ResNet-50 backbone pretrained on ImageNet. However, instead of only treating the Stanford Cars dataset as a flat 196-class problem, we additionally explore hierarchical classification strategies. Concretely, we design and compare models with one, two, and three prediction heads, where each head independently predicts one of the hierarchical levels: make, type, and model. Additionally, our approach incorporates a broader set of regularization and stabilization techniques, such as data augmentation, dropout, weight decay, and learning-rate scheduling. Finally, we also evaluate the impact of test-time augmentation (TTA).

3 Methods

3.1 Dataset and Pre-Processing??

- The dataset contains 16185 images of 196 classes of cars. The dataset is split into 8144 training images and 8041 test images. Each class has been split around a 50-50 split.
- Hierarchical Label Definition:

Hierarchy Level	Description	Example	Classification Difficulty
Head 1: Make	The manufacturer or brand of the vehicle. This is the coarse-grained class.	BMW	Easy (Highly distinct features/logos)
Head 2: Type	The general body style of the vehicle, inferred from the model name.	Sedan	Medium (Defined by shape/proportions)
Head 3: Model	The specific model and year of the vehicle (the original 196 classes).	3-Series Sedan 2012	Hard (Subtle visual differences)

3.2 Model Architecture

- **Backbone:** ResNet-50 (pretrained on ImageNet) without any modifications.
- **Multi-Task Heads:** The Data Architecture is based on the Shared-Bottom Multi-Task Learning paradigm. This approach uses a single Convolutional Neural Network (CNN) backbone to extract a universal, high-dimensional feature representation from the input image, which is then fed into multiple, distinct "heads," each responsible for a single classification task (e.g., Make, Model, or Type).
- **Multi-Head Architecture:** The architecture utilizes a multi-head design, based on the Shared-Bottom Multi-Task Learning paradigm, where the feature vector, F_{shared} , extracted by the backbone, is split and fed simultaneously into three independent, fully-connected (Dense) classification heads: Make, Type, and Model. This split allows the backbone to learn general, low-level visual characteristics shared by all tasks, while each head refines the features necessary for its specific, hierarchical classification level. The entire network is trained end-to-end by optimizing a single Combined Training Objective, L_{Total} , which is the weighted sum of the Categorical Cross-Entropy losses (L_{CCE}) from each head:

$$L_{Total} = w_{Make} \cdot L_{CCE}(y_{Make}, \hat{y}_{Make}) + w_{Type} \cdot L_{CCE}(y_{Type}, \hat{y}_{Type}) + w_{Model} \cdot L_{CCE}(y_{Model}, \hat{y}_{Model})$$

3.3 Training Strategies

- **Baseline:** First we set up a baseline for training which contained batch size = 32 with 15 epochs and a 0.0001 learning rate, where the ImageNet layers were frozen and only the fully connected layer was unfrozen. Then we unfroze the rest of the model parameters, to help the model recognize the shapes of the elements of the car models. Then we added the Make classification head that only predicts the make of the car (fx. BMW) while the first head was predicting the full label to make sure that the model is learning the hierarchy. Then later we added a third, Type classification head that only predicts the type of the car (fx. Sedan)
- **Data Augmentation, Normalization:** We added 4 different types of data augmentation and normalization
- **Random Resized:** and **Cropped Images** were first resized to a larger dimension (256x256) and then a 224×224 area was randomly cropped. This combination forces the model to learn features that are robust to variations in position, scale, and perspective (i.e., the car is not always perfectly centered).
- **Random Horizontal Flip:** Flips the image along the vertical axis with a 50
- **Random Rotation:** Images were randomly rotated up to ± 15 degrees. This provides rotational invariance, which is particularly useful for handling slight tilts or oblique angles in real-world images.
- **Color Jitter:** Randomly alters the brightness, contrast, and saturation of the images to make the model invariant to lighting conditions.
- **Normalization:** Input images were normalized using the mean and standard deviation of the ImageNet dataset, matching the pre-training conditions of the ResNet backbone.
- **Curriculum Learning:** We addressed curriculum learning with the 3 model head to make the model first learn easy (Make) and medium (Type) tasks before focusing on the hard (Model) task. To achieve it, we increased the number of epochs to 20 and in the 5 epochs, we froze the Model head, so it only trains on the Make and Type heads.
- **Hierarchical Label Smoothing (HLS):** While we were trying to squeeze out the last percentages of accuracy in training, we used HLS, to make the model penalize more the easy misses than the hard misses. Which means that for example mistaking a BMW M3 for a BMW 328i (Sibling error) shouldn't give the same loss as mistaking a BMW M3 for a Ford F-150 (Distant error). The technique we used for it is instead of a hard $[0, 1, 0, 0]$ target, use soft targets that give partial credit to siblings. While the hard target gives 100% weight loss for the correct car, while the soft targets give 90% to the correct car and 10% distributed among other cars in the same Make

3.4 Inference Strategies:

To evaluate the robustness of our model, we employ Test Time Augmentation (TTA) during the inference phase. Standard inference utilizes a single center crop of the input image. In contrast, our TTA protocol averages the softmax probability distributions of $N = 2$ views: the original image (x) and a horizontally flipped version ($flip(x)$). The final prediction \hat{y} is computed as:

$$\hat{y} = \operatorname{argmax} \left(\frac{1}{2} (P(x) + P(flip(x))) \right)$$

This approach exploits the model's learned invariance to geometric transformations (due to the data augmentation in Section 5.4) to stabilize and often improve final predictions. We assumed that it is going to slightly increase our accuracy during testing.

4 Results

Organize results by "Research Question" rather than date.

4.1 Establishing the "Hierarchy Gap" (Baselines)

- **Objective:** Show that flat classifiers fail to capture relationships
- **Data:** Compare the Frozen Baseline (42% Acc) vs. Unfrozen (76% Acc).
- **Key Finding:** Even with decent accuracy, the "Gap" between Make Accuracy (85.5%) and Model Accuracy (75.9%) was nearly 10%, indicating the model was guessing Models without knowing the Brand.

4.2 The Impact of Regularization & Class Balancing

- **Objective:** Solving the overfitting problem.
- **Data:** Show the jump from 77% (Phase 3) to 86.6% (Phase 4) just by adding Data Augmentation.
- **Observation:** Note that Class Balancing (Phase 5) helped rare classes but slightly hurt overall consistency (The "Robin Hood" effect).

4.3 Architectural Ablation: The Necessity of "Type"

- **Objective:** Solving the overfitting problem.
- **Data:** Compare Experiment 8 (2-Head Curriculum: 86.49%) against Experiment 7 (3-Head Curriculum: 86.15% - initial) and Experiment 9/10 (Final 3-Head: 89%).
- **Key Finding:** While 3-Head initially struggled due to interference, once optimized (see next section), it outperformed the 2-Head approach, proving that the "Type" layer acts as a necessary semantic bridge.

4.4 Optimization Dynamics: Interference vs. Curriculum

- **Objective:** Solving the "Task Interference" problem in Multi-Task Learning.
- **Data:** Contrast Experiment 6 (3-Head No Curriculum: 85.36%) vs. Experiment 7 (3-Head With Curriculum: 86.15%).
- **Key Finding:** Without curriculum, gradients conflicted. Freezing the hard head allowed the backbone to learn stable features first.

4.5 SOTA Performance: Label Smoothing & LR Scheduler

- **Objective:** Pushing the limit.
- **Data:** Present the final model (Experiment 10) achieving 89.07% Top-1 Accuracy.
- **Key Finding:** The Scheduler + HLS closed the consistency gap significantly.

4.6 The Impact of Inference Strategies

either talk about the results of tta here or above in SOTA, report the final number (88.57%)

5 Discussion

This is the most critical section for grading. Interpret the patterns.

5.1 The "Frankenstein Car" Problem

- Discuss Hierarchical Consistency.
- In early experiments, consistency was low (90%). The model would predict "Toyota" (Make) and "Honda Civic" (Model).
- By Experiment 9 (HLS), consistency reached 96.6%, and finally 97.66% with the scheduler. This proves the model learned the taxonomy, not just pixel patterns.

5.2 The Role of "Type" as Scaffolding

- Analyze why 3_head_curriculum eventually beat 2_head_curriculum.
- The "Type" head (Sedan, SUV, Coupe) provides Intermediate Scaffolding. It is easier to learn than "Model" but provides more structural information than "Make." It bridges the semantic gap.

5.3 The "Free Lunch" of Training Schedules

- Discuss the final experiment (LR Scheduler).
- ou gained 1.5% accuracy (87.9% \rightarrow 89.07%) just by changing the learning rate schedule. This indicates the architecture was sound, but the optimizer needed "fine-grained" control to settle into the sharp minima of the loss landscape.

5.4 Robustness via Inference Ensembling

Explain how TTA serves as a proxy for measuring model robustness, argue that this proves our model is robust and "production-ready"

6 Conclusion

Conclude that while ResNet50 is powerful, structuring the learning process (Curriculum) and enforcing taxonomy (Multi-head + HLS) creates a model that is not only more accurate but logically robust.
